The Empirical Twins

When Holism and Its Negation Make the Same Predictions: a comparison-proof convergence of two opposite theses

Eduardo Ramos Mendoza

2026

Abstract

Two companion papers take opposite maximal theses as far as each will go. One argues that *everything is constitutively related* — every system a holon, the universe the maximal holon. The other argues that *nothing is related* — every thing an orphan, the whole itself an orphan, the connections false. This paper sets the two side by side and asks the only question a comparison can settle: when a thesis and its *exact negation* are each pushed to their strongest form, what is the relation between them? The answer is established by three comparison-proof moves. First, **structural isomorphism**: the two arguments are the *same* argument — the same three readings, the same vacuity hazard, the same minimal framework, the same consequence-bearing walls, the same reflexive capstone, the same deflationary verdict. Second, **empirical equivalence**: in their strong, ontological readings the two are *empirical twins* — each consistent with every observation, neither forbidding what the other permits; holism's unrestricted-composition lens and disconnection's occasionalist re-description are one vacuity move run from opposite ends. Third, a **shared collision**: the one contentful form of *each* thesis dies on the *same* physics — quantum non-separability refutes "every system is near-decomposable" and "every whole is separable" alike. The convergence yields a single result: the **all-related ↔ nothing-related axis is a choice of descriptive lens projected onto the world, not a fact read off it**, and what *survives* of both opposites is one and the same epistemic stance — the carving is the modeller's, the signature is relative to a declared frame. The comparison earns exactly one modest, empirical datum about the world itself: entanglement says *no* to both extremes, so the world is neither a heap of orphans nor a seamless whole, but relationally structured in a specific, measurable way.

1 Introduction

1.1 Two papers, one comparison

This is the third of three papers, and it is parasitic on the first two. The first takes the holist intuition to its maximum: a system is intelligible only through its place in a nested whole, every system is holonically organised, and "the principal holon … [is] the universe itself … the maximal container." The second takes the *opposite* intuition to *its* maximum: no relation of any kind holds between one thing and another; "everything is an orphan connected to nothing … the whole itself is an orphan; the connections are false." Each thesis received the same treatment — a SOTA sweep, a frozen statement, a minimal framework for its empirical content, and a deflationary verdict — and each was found mostly false but instructively so.

Two finished analyses of two contradictory theses invite the one question neither paper could ask from inside itself: **what is the relation between a maximal thesis and its exact negation, once both are made as strong as they can be?** Naively, contradictories cannot both be right, so at most one can be an ontological discovery; one expects the comparison to

award the prize to a winner. It does not. The comparison's finding is that the two are far more alike than their opposite content suggests — alike in form, alike in what observations they (fail to) forbid, alike in where they die — and that the likeness is not a coincidence but a diagnosis of the whole axis they span.

1.2 Three readings of the comparison

A comparison of two opposite theses admits three readings, which must never be allowed to share credit.

- **Coincidence.** The two papers resemble each other only because one author wrote both with one method; the resemblance is a fact about the authorship, not about the theses. If this is all there is, the comparison teaches nothing about holism or disconnection.
- **Shared error.** The two theses fail *the same way* because they share a hidden bad assumption; expose it and both improve. This is interesting but still a claim about the arguments, not about the world.
- **Shared lens.** The two are *empirically equivalent* in their strong readings: each re-describes the other's data without remainder, so neither is an ontological discovery, and the entire all-related/nothing-related axis is a descriptive lens projected onto the world rather than a structure found in it. This is the reading the paper will defend — and it is the strongest, because it is the only one that turns the comparison into a result about the theses' *empirical content*.

The three are ordered by how much they claim, and the paper's burden is to earn the third without smuggling it in: the resemblance must be shown to be structural *and* empirical *and* to survive the one place the world actually adjudicates, not merely asserted because the two papers rhyme.

1.3 The claim, and the comparison-proof method

The claim.

> In their strong, ontological readings, holism and disconnection are **empirical twins**: each is consistent with every possible observation, neither forbids an observation the other permits, and each survives only as a heuristic *lens* plus an *unfalsifiable metaphysics*. The all-related $\leftrightarrow$ nothing-related axis is therefore a choice of descriptive lens, not a fact about the world; and what survives of *both* opposites is the **same epistemic stance** — that the decomposition is the modeller's, and the holonic signature or the constructed connection is relative to a declared frame. The comparison earns exactly one fact about the world: the contentful form of each thesis collides with quantum non-separability, so the world is *neither* a mere aggregate of orphans *nor* a seamless undifferentiated whole.

This claim is made in the **necessary-only** register inherited from both papers: it concerns the *strong/ontological* readings; the weak/lens readings of each thesis are retained, not refuted; and the metaphysical ancestors of both (Leibniz and Malebranche on one side, General Systems Theory and Integrated Information Theory on the other) are *reclassified* as coherent-but-idle, never declared false.

The method. The convergence is established by three moves, in strict order, each a comparison a reader can re-run against the two source papers:

1. **Structural isomorphism** (section 2): the two arguments are near-isomorphic, shown by an explicit element-by-element map. This is the weakest move on its own (it could be mere coincidence, section 1.2), so it is only the entry.

2. **Empirical equivalence** (section 3): each thesis re-describes the other's data with no observable remainder — holism's unrestricted-composition lens and disconnection's occasionalist re-description are the same vacuity move from opposite ends — and both reduce, when made contentful, to a claim about a *(system, decomposition, signature)* tuple, with the same open sufficiency problem inherited at the same joint. This upgrades coincidence to twinhood.

3. **The shared collision** (section 4): the contentful form of *each* thesis is refuted by the *same* fact — quantum non-separability. A thesis and its negation that die on one experiment are not two discoveries; they are two lenses meeting the one place the world says "no."

Roadmap. Section 2 lays out the structural isomorphism. Section 3 proves the empirical-twin theorem. Section 4 draws the fits: the shared collision (and the modest positive datum it earns), the convergence of the two surviving cores into one epistemic stance, and the smaller mirrored details. Section 5 states what the convergence yields, the verdict, and what it does not claim. The appendix gives the claim-by-claim correspondence table.

1.4 Contributions

This paper makes the following contributions.

- An **empirical-twin theorem**: a demonstration that the strong holonic and strong disconnection theses are empirically equivalent, established by structural isomorphism + lossless mutual re-description + a shared refutation, not by assertion.
- A **structural isomorphism map** (section 2, and the appendix table): an element-by-element correspondence between the two papers' architectures, re-runnable against the sources.
- A **shared-collision result**: the observation that quantum non-separability is the single fact that refutes the contentful form of *both* opposites, and the modest positive datum this earns — the world is specifically relationally structured, neither orphan-heap nor seamless whole.
- A **convergence of surviving cores**: the finding that what survives each thesis (near-decomposability relative to a pre-registered partition; structure-dependent construction relative to a system) is one epistemic stance — map $\neq$ territory, the carving is the modeller's.
- A **lens diagnosis** of the all-related/nothing-related axis: the deflationary conclusion that the axis is a descriptive choice projected onto the world, with the honest limit (section 5) that this is a claim about the two theses' empirical content, not a proof that either metaphysics is false.

2 The structural isomorphism: one architecture, two contents

The first move is the cheapest and the most visible: the two papers are built from the same parts in the same order. This is not yet a claim about the world — two documents by one author

with one method might rhyme by construction (section 1.2, the coincidence reading) — but it is the necessary entry, because the empirical equivalence of section 3 is the structural isomorphism *cashed at the level of observations*. The full element-by-element correspondence is tabulated in section A; the load-bearing parallels are these.

The same three readings. Each paper opens by splitting its thesis into a *weak/lens* reading (true and nearly contentless), a *strong/ontological* reading (the announced thesis, argued to be coherent metaphysics rather than science), and an *epistemic/methodological* reading (the survivor). The split is not a stylistic tic; it is forced by the same hazard — a universal predicate that applies to everything typically forbids nothing — and both papers name that hazard, *up front*, as the thing the rest of the argument must escape.

The same vacuity hazard, from documented ancestors. The holonic paper grounds the hazard in the fate of General Systems Theory — "we always pay for generality by sacrificing content" (Boulding 1956) — in Putnam's triviality result (Putnam 1988), and in Integrated Information Theory's published charge of unfalsifiable panpsychism. The disconnection paper grounds the *same* hazard in occasionalism and the pre-established harmony (Leibniz 1714; Malebranche 1674), doctrines engineered to be indistinguishable from ordinary interaction. Different ancestors, identical diagnosis: a doctrine consistent with every observation is a re-description, not a theory (Popper 1959).

The same minimal framework. Each paper locates the one place its thesis acquires testable content and states the smallest set of commitments, fixed before the data, that give it that content. They are structurally identical three-tuples:

Role of the commitment	Holonic paper	Disconnection paper
A declared decomposition	a pre-registered **partition** into modules	a declared **decomposition** into intrinsic-property bearers
A declared frame on it	a pre-registered **timescale** (Weinberger 2020)	a declared **supervenience base** (Lewis 1986)
A risky counterfactual	a **contraction** counterfactual ($\varepsilon < \varepsilon_c$, Bousquet and Slotine 2015)	a **no-non-separable-whole** counterfactual

In both, pre-registration is the institutional implementation; in both, the framework is proved *minimal* (each commitment required, no pair sufficient, no fourth doing additional logical work); and in both, the framework is claimed **necessary only**, with sufficiency left as an inherited open problem — the Putnam–Chalmers question for the holonic thesis (Chalmers 1996), the non-uniqueness of the occasionalist re-description for the disconnection thesis.

The same consequence-bearing walls. Each paper draws its empirical commitment as the *contraposition class* — the systems it calls impossible. And here the parallel sharpens into the hinge of the whole comparison: both contraposition classes *contain the same member*, quantum non-separability (section 4).

The same reflexive capstone, the same deflationary verdict. Each turns its framework on its own maximal object — "the universe is the principal holon" / "the totality is an orphan" — and finds it ill-formed by an equivocation the single key word hides ("holon" trades on Koestler's Janus definition (Koestler 1969); "orphan" trades on *no external relatum* versus *no internal relations*). Each closes deflationary, reclassifies its ancestors as coherent-but-idle rather than false, states a surviving core as a prohibition/lens, and appends an explicit "what this does not claim."

Seven shared structural elements, in the same order, is past what coincidence comfortably explains. But structure alone cannot decide between the three readings of section 1.2; for that the resemblance must be shown to hold *at the level of observations*. That is the next section.

3 The empirical-twin theorem

Structure can rhyme by accident; observations cannot. This section upgrades the isomorphism of section 2 to the claim that decides the comparison: in their strong, ontological readings, holism and disconnection are **empirically equivalent** — neither forbids an observation the other permits.

3.1 One vacuity move, run from opposite ends

Each strong thesis owes its universality to a *total, lossless re-description* of the same data, and the two re-descriptions are mirror images.

Holism's lens is unrestricted composition: under classical extensional mereology every individual is a part of the universal fusion, so *every* system is, trivially, a part of some whole and a whole of some parts. Anything whatever can be *described* as a holon; the description adds nothing measurable and excludes nothing. *Disconnection's lens* is the occasionalist re-description: any relational fact $R(a, b)$ is rewritten as two intrinsic reactions $f_a(\sigma), f_b(\sigma)$ plus an off-stage coordination assumption, reproducing every observable consequence of R and adding nothing measurable (Leibniz 1714; Malebranche 1674).

These are the *same* move. One says "everything is inside the whole"; the other says "everything is sealed in the part"; both are notational re-paintings of an unchanged set of facts, and both were built — by the systems theorist's universal quantifier on one side, by Leibniz and Malebranche on the other — precisely so that no observation could disturb them. A predicate that applies to everything and a predicate that applies to nothing forbid the same thing: nothing.

3.2 The same contentful reduction — and the same inherited gap

Each thesis becomes contentful at exactly one point, and at that point both collapse to a claim of the *same form*: a property not of a system but of a *(system, decomposition, signature)* tuple.

The holonic claim acquires content as *near-decomposability under a pre-registered (partition, timescale)*: a measurable timescale gap, present or absent relative to the declared decomposition. The disconnection claim acquires content as *separability under a declared decomposition*: the world's state supervenes on the parts' intrinsic properties, or it does not, relative to the declared bearers (Lewis 1986). In neither case is the property read off the world *simpliciter*; in both it is read off a (system, decomposition, signature) triple the modeller must declare first. And in both, the declaration is exactly where the open problem lives: the holonic thesis inherits the Putnam–Chalmers question of whether pre-registration *completely* blocks the post-hoc-partition freedom (Chalmers 1996); the disconnection thesis inherits the symmetric question of whether any decomposition-fixing rule completely blocks the occasionalist re-description. Same joint, same gap, neither solved.

3.3 The theorem

Assemble the pieces. In their strong/ontological readings:

> **Empirical-twin theorem.** The strong holonic thesis and the strong disconnection thesis are empirically equivalent: (i) each is consistent with every possible observation (by the mirror lenses of section 3.1); (ii) neither forbids an observation the other permits; (iii) each survives only in two registers — a heuristic *lens* that organises description, and an *unfalsifiable metaphysics* that asserts more than any measurement could check (for the disconnection thesis, the metaphysics survives only in its

occasionalist register — its explanatory "signals" form self-refutes, per that paper's self-refutation wall, an asymmetry section 5.2 returns to).

The corollary is the comparison's verdict on the three readings of section 1.2. Coincidence is too weak (the resemblance reaches all the way down to what the theses forbid, which authorship does not fix). Shared-error is too narrow (there is no single bad premise to remove — the equivalence is structural, not a slip). What remains is the **shared-lens** reading: *a doctrine and its negation that make the same predictions are both lenses.* At most one of two contradictories can be an ontological discovery, and when the two are empirically indistinguishable, the parsimonious conclusion is that *neither* is — the all-related ↔ nothing-related axis is a descriptive choice projected onto the world, not a structure found in it.

One guard against over-reading. The theorem is about the *strong* readings. The *contentful* readings — near-decomposability, separability — do forbid things, and there the two theses are not idle: they make risky, pre-registrable claims. But this does not break the twinhood; it sharpens it, because the contentful readings do not merely both become testable — they both meet their refutation at the *same* fact. That is the third move.

4 The fits: where the opposites connect

The twin theorem says the two strong theses are empirically equivalent. This section draws the *connections that follow* — the details that, once the comparison is made, are seen to fit: a single fact that refutes both, two surviving cores that turn out to be one, and a set of smaller mirrored failures.

4.1 The shared collision — and the one fact the comparison earns

The contentful readings diverge into testability (section 3.3), and then meet again at their refutation. *Quantum non-separability is in the contraposition class of both papers.*

For the disconnection thesis the collision is direct: its contentful form is separability — the world supervenes on the intrinsic properties of its parts plus their arrangement — and entangled states are *non-separable*, carrying joint facts irreducible to any assignment of intrinsic properties to the parts. Bell's theorem rules out every locally-separable model (Bell 1964); the CHSH inequality $|S| \leq 2$ bounds them (Clauser et al. 1969); experiment crosses the bound (Aspect et al. 1982; Healey and Gomes 2022). For the holonic thesis the collision is equally direct from the opposite side: entanglement is the *extreme of the integrative pole* — the whole is prior to the parts, the "parts" are not semi-autonomous — so a clean near-decomposable split into quasi-independent modules *fails*, and entanglement sits squarely in the holonic paper's own contraposition class.

So the *same fact* bears on "every whole is separable" and "every system is near-decomposable" at once — though not symmetrically: it refutes disconnection's *live* contentful core (separability), whereas for holism it refutes only the universal "any" the bounded thesis had already disowned, while *instantiating* holism's integrative pole (the whole prior to its parts). The shared collision is real but asymmetric — it kills one twin's core and confirms the other's intuition, puncturing only its over-reach. Still, neither *universal* survives the one experiment: two over-claims meeting the single place the world says "no."

And that "no" is the one positive datum the whole comparison earns. The world is **not** a mere aggregate of orphans — non-separability forbids it. But neither is it a seamless, undifferentiated whole — entanglement is *specific*: particular systems carry particular irreducible joint facts, against a background where most things are, to excellent approximation, separable and locally

describable. The world is therefore **relationally structured in a specific, measurable way** — which is neither extreme, and is exactly the territory that ontic structural realism (Ladyman and Ross 2007) and priority monism's opponents map. This datum is modest, empirical (V1), and ontological; it is the only ontology the comparison licenses, and it is bought with physics, not metaphysics.

4.2 Two surviving cores, one epistemic stance

Strip each thesis to what survives its walls and the two residues, stated as each paper states them, turn out to be the same stance wearing two vocabularies.

The holonic survivor is *near-decomposability relative to a pre-registered (partition, timescale)*: a system is holonic, contentfully, only relative to a declared decomposition under which the timescale-gap signature clears threshold. The disconnection survivor is *structural-determinist projectivism*: a system's response is shaped by its own structure, so the connections it reads are in part its construction, relative to that structure (Maturana and Varela 1980). Read side by side, both say one thing: **the carving is the modeller's, and the signature — the holonic gap, the constructed connection — is relative to a declared frame, not an intrinsic readout of the world.** Map $\neq$ territory, in both. The metaphysics (everything-related / nothing-related) dies in both; the *lens* survives in both; and the two lenses are the same lens — an epistemic, frame-relative stance about how a modeller carves a system, not a thesis about how the world is knit. The opposites converge not at a compromise midpoint but at a shared *altitude*: both, demetaphysicised, are methodology.

4.3 The smaller mirrored details

Three further fits, each a place where the two papers' parts slot together once aligned.

The capstones fail for one reason. "The universe is the principal holon" is a category error on Koestler's Janus definition (Koestler 1969): the maximal whole has no super-whole, so it cannot be the part-and-whole a holon must be. "The totality is an orphan" equivocates between *no external relatum* (trivially true of the maximal container) and *no internal relations* (the contested claim). These are the *same* failure: both apply a relational/partition predicate to the one object that has no exterior, and both break on the missing exterior. The maximal object refutes the maximal form of either thesis for the same structural reason — the one mirror that genuinely is symmetric.

The ancestors are reclassified by one verdict. Holism's vacuity ancestors (General Systems Theory, Integrated Information Theory) and disconnection's coherence ancestors (Leibniz's windowless monads, Malebranche's occasionalism) receive the same treatment in both papers: coherent metaphysics, reclassified as empirically idle, never declared false. The reclassify-not-refute move is one move, applied to two lineages.

The antithesis sits at the convergence. Ontic structural realism — relations fundamental, relata derivative — is the named antithesis of the disconnection thesis (relata without relations) and, read from the other side, the natural description of the holonic thesis's hardest counterexample (entanglement as whole-before-parts). The position that opposes *both* extremes is the same position (Ladyman and Ross 2007), and it is the one the shared collision (section 4.1) points to. The opposites do not just resemble each other; they point, together, at a third thing that is neither.

5 What the convergence yields, and the verdict

5.1 Three yields

The comparison returns three things, in descending order of certainty.

An axis that is a lens. The all-related ↔ nothing-related opposition, in its strong ontological form, is not a factual dispute the world will settle for one side. It is a choice of descriptive lens projected onto an unchanged set of facts (section 3). The two poles are empirical twins; the debate between them, conducted as metaphysics, forbids no observation and so decides nothing. This is the deflationary core, and it is the symmetric completion of each paper's own verdict: each found *its* thesis idle in the strong reading; the comparison finds the *whole axis* idle, because a pole and its negation cannot both be discoveries and here neither is.

A residue that is a method. What survives is not a winner but a shared stance: the carving is the modeller's, and the holonic signature or the constructed connection is relative to a declared frame (section 4.2). Demetaphysicised, holism and disconnection are the same methodology — a disciplined, frame-relative way of modelling — and that methodology is worth keeping precisely because it makes no ontological claim.

A datum that is the world's. The comparison earns exactly one fact about the world, and it is modest and empirical: quantum non-separability refutes the contentful form of both extremes (section 4.1), so the world is neither an aggregate of orphans nor a seamless whole, but relationally structured in a specific, measurable way. This is the one place the comparison touches ontology, and it does so with physics (V1), not with either metaphysics.

5.2 Verdict

Deflationary, and symmetric in empirical content. Two maximal theses, taken to their strongest forms and set against each other, dissolve together — same empirical idleness, one shared experimental kill — though the dissolution is *twinned, not identical*. The symmetry is of empirical content, not of structure: the architectures are near-isomorphic but the disconnection thesis carries a second, independent kill its opposite lacks (its explanatory form *self-refutes*, where holism's matching wall is a vacuity hazard the holonic criterion is built to clear), and the shared collision is asymmetric (it refutes disconnection's live separability core while merely puncturing holism's already-disowned universal form, and *instantiating* holism's integrative pole). The prize the naive comparison expected to award — to holism or to disconnection — goes to neither; it goes, in a diminished and empirical form, to a third position that opposes both, and even that is held only as far as the physics reaches. The reclassification is symmetric too: Leibniz and Malebranche, General Systems Theory and Integrated Information Theory are all coherent metaphysics, idle by construction, none refuted. The trilogy's net result is therefore not a metaphysics but its absence, plus a method and one fact.

5.3 What this paper does not claim

- **Not that the two theses are the same thesis.** They are contradictory in content; they are twins in *empirical content* (both idle in the strong reading), not identical in meaning. Twinhood is a claim about what they forbid, not about what they say.
- **Not that either metaphysics is false.** The strong readings are empirically idle, not refuted; unfalsifiable metaphysics is legitimate metaphysics (section 3.1). The charge is over-claiming — presenting a lens as a discovery — not falsehood.

- **Not that relations are metaphysically fundamental.** Ontic structural realism is named as the position the shared collision *points to*, not assumed or proved. The paper claims only that the contentful form of each thesis collides with experimental facts (Bell-violation, non-separability) that any interpretation must accommodate.
- **No contested interpretation promoted to fact.** The collision rests on V1 results; the separability-preserving escapes (superdeterminism and the like) remain V3 and, as both source papers note, buy their rescue at the price of the very vacuity under diagnosis.
- **Not a validation of the method that produced the papers.** Whether the analysis loop yields better results than a simpler process is a separate, measured question, treated elsewhere; this paper assumes the two source papers, it does not certify the apparatus.
- **Not a refutation of either source paper.** The convergence *uses* both, intact; it adds a relation between them, and removes nothing from either.

5.4 The honest ceiling

Two limits bound the result. First, its register: the empirical-twin theorem (section 3.3) is an *analytical, argued* result — a reasoned demonstration of equivalence, not an experiment; only the shared collision (section 4.1) is itself *measured* (V1). The verdict's certainty is the certainty of an argument, and inherits the open sufficiency gap both papers carry (section 3.2): strictly, the twins are empirically equivalent *to the extent* that neither's post-hoc re-description is fully closed, which neither paper establishes.

Second, its provenance: this paper compares two analyses by one author, written with one method, and a shared author is a confound an isomorphism claim must own. The defence is that the load-bearing moves are re-runnable by a reader against the two source papers — the structural map (section A) is checkable, the mirror lenses are documented, the shared collision is public physics — so the result does not rest on trusting the author's framing. But the stronger test is external: a comparison drawn by someone who wrote neither paper would carry weight this one cannot give itself. That external check is invited, not pre-empted.

A The correspondence table

The element-by-element map underwriting section 2. Each row is a structural slot; the two columns are how each paper fills it. A reader can re-run the comparison by opening the two source papers at the named parts. The table is the structural-isomorphism claim in checkable form (section 1.2, the move that coincidence cannot fully explain and that section 3 cashes empirically).

Structural slot	Holonic paper (all-related)	Disconnection paper (nothing-related)
Strong thesis	every system is holonically organised; the universe is the maximal holon	no relation exists; every thing is an orphan; the totality is an orphan
Weak / lens reading	any system is *describable* as holonic (unrestricted composition)	a system's response is structure-dependent, not input-dictated (constructivism)
Vacuity hazard	General Systems Theory's emptiness; Putnam-triviality; IIT's panpsychism charge	occasionalism / pre-established harmony: empirically equivalent to interaction
Where content lives	near-decomposability (a timescale-gap signature)	separability (Humean supervenience)
Commitment 1 (decomposition)	a pre-registered partition into modules	a declared decomposition into intrinsic-property bearers
Commitment 2 (frame)	a pre-registered timescale	a declared supervenience base
Commitment 3 (counterfactual)	contraction: $\varepsilon < \varepsilon_c$ leaves siblings invariant	no admissible perturbation yields a non-separable whole
Institutional implementation	pre-registration	pre-registration
Claimed status	necessary only; sufficiency = the open Putnam–Chalmers problem	necessary only; sufficiency = the open re-description non-uniqueness
Contraposition class (shared member)	turbulence, SOC, **quantum non-separability**	**quantum non-separability**
Distinctive structural kill	the partition-presupposition wall (the signature is partition-relative)	the self-refutation wall (a received signal *is* a relation)
Capstone failure	category error on Koestler's Janus definition	equivocation: no external relatum vs. no internal relations
Surviving core (a lens)	near-decomposability relative to a pre-registered partition	structural-determinist projectivism relative to a system's structure
Reclassified ancestors	GST, IIT — coherent metaphysics, idle	Leibniz, Malebranche — coherent metaphysics, idle
The position it points to	(a flat description is the foil; the integrative extreme is entanglement)	ontic structural realism / relational QM (relations without relata)

The bottom four rows are where the opposites stop merely mirroring and begin to *fit* (section 4): one shared contraposition member (the collision), two surviving cores that read as one epistemic stance, two capstones that fail on the one object with no exterior, and a single third position — ontic structural realism — that opposes both poles and is what the shared collision points toward.
